Experiment No. 9: Binary Search Tree Operations Aim :
Implementation of Binary Search Tree ADT using Linked List.

Objective:

- 1) Understand how to implement a BST using a predefined BST ADT.
- 2) Understand the method of counting the number of nodes of a binary tree.

Theory:

A binary tree is a finite set of elements that is either empty or partitioned into disjoint subsets. In other words nodes in a binary tree have at most two children and each child node is referred to as left or right child.

Traversals in trees can be in one of the three ways: preorder, postorder, inorder.

Preorder Traversal

Here the following strategy is followed in sequence

1. Visit the root node R
2. Traverse the left subtree of R
3. Traverse the right subtree of R

Description	Output
Visit Root	A
Traverse left sub tree – step to B then D	ABD
Traverse right subtree – step to G	ABDG
As left subtree is over. Visit root , which is already visited so go for right subtree	ABDGC
Traverse the left subtree	ABDGCEH
Traverse the right sub tree	ABDGCEHIF

Inorder Traversal

Here the following strategy is followed in sequence

1. Traverse the left subtree of R
2. Visit the root node R
3. Traverse the right sub tree of R

Description	Output
Start with root and traverse left sub tree from A-B-D	D

As D doesn't have left child visit D and go for right subtree of D which is G so visit this.	DG
Backtrack to D and then to B and visit it.	DGB
Backtrack to A and visit it	DGBA
Start with right sub tree from C-E-H and visit H	DGBAH
Now traverse through parent of H which is E and then I	DGBAHEI
Backtrack to C and visit it and then right subtree of E which is F	DGBAHEICF

Postorder Traversal

Here the following strategy is followed in sequence

1. Traverse the left subtree of R
2. Traverse the right sub tree of R
3. Visit the root node R

Description	Output
Start with left sub tree from A-B-D and then traverse right sub tree to get G	G
Now Backtrack to D and visit it then to B and visit it.	GD
Now as the left sub tree is over go for right sub tree	GDB
In right sub tree start with leftmost child to visit H followed by I	GDBHI
Visit its root as E and then go for right sibling of C as F	GDBHIEF
Traverse its root as C	GDBHIEFC
Finally a root of tree as A	GDBHIEFCA

Algorithm

Algorithm: PREORDER(ROOT)

Algorithm :

Function Pre-order(root)

- Start
- If root is not null then

Display the data in root

Call pre order with left pointer of root(root -> left)

Call pre order with right pointer of root(root -> right)

- Stop

Algorithm: INORDER(ROOT)

Algorithm :

Function in-order(root)

- Start
- If root is not null then

Call in order with left pointer of root (root -> left)

Display the data in root

Call in order with right pointer of root(root -> right)

- Stop

Algorithm: POSTORDER(ROOT)

Algorithm :

Function post-order (root)

- Start
- If root is not null then

Call post order with left pointer of root (root -> left)

Call post order with right pointer of root (root -> right)

Display the data in root

- Stop

Code:

```
#include

```

Output:

```
*****MAIN MENU*****
1. Insert Element
2. Preorder Traversal
3. Inorder Traversal
4. Postorder Traversal
5. Find the smallest element
6. Find the largest element
7. Delete an element
8. Count the total number of nodes
9. Count the total number of external nodes
10. Count the total number of internal nodes
11. Determine the height of the tree
12. Find the mirror image of the tree
13. Delete the tree
14. Exit
Enter your option : 1
Enter the value of the new node : 1
Enter the value of the new node : 2
Enter the value of the new node : 4
Enter your option : 3
2 1 4
Enter your option : 14
```

Conclusion:

Write a function in C program to count the number of nodes in a binary search tree?

```
#include <stdio.h>
```

```
#include <stdlib.h>
```

```
// Definition for a BST
```

```
node struct Node {    int
data;    struct Node* left;
struct Node* right;
};
```

```
// Function to create a new BST node
```

```
struct Node* createNode(int data) {
    struct Node* newNode = (struct Node*)malloc(sizeof(struct Node));    newNode->
data = data;
    newNode->left = newNode->right = NULL;
return newNode;
```

```
}
```

```
// Function to insert a new node into the BST  
struct Node* insert(struct Node* root, int data)
```

```
{   if (root == NULL)      return  
createNode(data);   if (data < root->data)  
root->left = insert(root->left, data);   else if  
(data > root->data)      root->right =  
insert(root->right, data);   return root;  
}
```

```
// Function to count the number of nodes in the  
BST  
int countNodes(struct Node* root) {   if  
(root == NULL)      return 0;  
    return 1 + countNodes(root->left) + countNodes(root->right);  
}
```

```
int main() {   struct Node*  
root = NULL;
```

```
    // Insert elements into the  
BST   root = insert(root, 10);  
root = insert(root, 5);   root =  
insert(root, 15);   root =  
insert(root, 3);   root =  
insert(root, 7);   root =  
insert(root, 12);   root =  
insert(root, 18);
```

Department of Artificial Intelligence & Data Science

```
// Count the number of nodes in the BST    int  
nodeCount = countNodes(root);    printf("Number of  
nodes in the BST: %d\n", nodeCount);    return 0;  
}
```

2. Describe a situation where binary search is significantly more efficient than linear search.

Binary search is significantly more efficient than linear search when searching for a specific item in a sorted list or array. In this scenario, binary search can quickly find the target item by repeatedly halving the search space, leading to much faster search times compared to linear search, which checks each item one by one.

3. Explain the concept of "binary search tree." How is it related to binary search, and what are its applications?

A Binary Search Tree (BST) is a data structure where each node has two child nodes, and it's organized such that items on the left are smaller, and items on the right are larger than the parent node. It's related to binary search as it allows for efficient searching, insertion, and deletion operations.

Applications:

1. Efficient searching, insertion, and deletion in databases and data structures.
2. Implementing data structures like sets and maps in programming.
3. In file systems for quick file retrieval.
4. Network routing algorithms for efficient data routing.
